Present Value

Formula 1. Given constant discount rate r, a cash flow stream $(C_1, C_2,...)$ has **present value** of

$$PV(C_1, C_2, \dots) = \sum_{t=0}^{\infty} PV(C_t)$$
$$= \frac{C_1}{(1+r)} + \frac{C_2}{(1+r)^2} + \dots$$

Including C_0 , usually a cash outflow (i.e. payment) gives the **net present value (NPV)**. Note that r can be an interest rate on a bond or the cost of capital, depending on context.

Formula 2. A perpetuity that pays C each period has a present value of

$$PV = \frac{C}{(1+r)} + \frac{C}{(1+r)^2} + \dots = \frac{C}{r}.$$

Formula 3. A perpetuity with growth has a present value of

$$PV = \frac{C_1}{(1+r)} + \frac{(1+g)C_1}{(1+r)^2} + \frac{(1+g)^2C_1}{(1+r)^3} + \dots$$
$$= \frac{C_1}{r-q},$$

where g is the growth rate of the payment each period. This formula is only valid if g < r.

Formula 4. An **annuity** that pays C each period for T periods has a present value of

$$PV = \frac{C}{(1+r)} + \frac{C}{(1+r)^2} + \dots + \frac{C}{(1+r)^T}$$
$$= \frac{C}{r} \left[1 - \left(\frac{1}{1+r} \right)^T \right].$$

Formula 5. An annuity with growth that pays C each period for T periods has a present value of

$$PV = \frac{C}{(1+r)} + \frac{(1+g)C}{(1+r)^2} + \dots \frac{(1+g)^{T-1}C}{(1+r)^T}$$
$$= \frac{C}{r-g} \left[1 - \left(\frac{1+g}{1+r}\right)^T \right],$$

where g is the growth rate of the payment each period.

Formula 6. A coupon bond with face value FV, coupon payments C, and maturity of T periods, has present value of

$$PV = \frac{C}{(1+r)} + \frac{C}{(1+r)^2} + \dots + \frac{C}{(1+r)^T} + \frac{FV}{(1+r)^T}$$
$$= \frac{C}{r} \left[1 - \left(\frac{1}{1+r} \right)^T \right] + \frac{FV}{(1+r)^T}.$$

Formula 7. The resale value of a perpetuity after T periods is

$$RV = \frac{C}{r} \left(\frac{1}{1+r} \right)^T.$$

Capital Budgeting Rules

Formula 8. Given constant discount rate r, a cash flow stream $(C_1, C_2, ...)$ with cost $C_0 \leq 0$ has **net present value** of

$$NPV = C_0 + \sum_{t=0}^{\infty} PV_r(C_t)$$
$$= C_0 + \frac{C_1}{(1+r)} + \frac{C_2}{(1+r)^2} + \dots$$

If NPV > 0, then the stream of discounted cash flows exceeds the cost and thus the project is worth doing. Given a choice of projects, a firm will choose the project that gives the highest NPV.

Formula 9. For cash flow stream $(C_0, C_1, C_2, ...)$, the internal rate of return (IRR) is the number satisfying

$$0 = C_0 + \frac{C_1}{(1 + IRR)} + \frac{C_2}{(1 + IRR)^2} + \dots$$

For this to be satisfied, we must have at least two C_i, C_j of opposite signs. We might find multiple solutions, in which case there is no well-defined IRR.

A project $(C_0, C_1, ...)$ with cost of capital r should be accepted whenever the IRR is well-defined and is greater than r. (Intuitively, accept the project if r is low enough, i.e. low enough borrowing cost.)

Formula 10. For cash flow stream $(C_0, C_1, C_2, ...)$, the **profitability index** is

$$PI = \frac{PV(C_1, C_2, \ldots)}{|C_0|}.$$

Intuitively, it is the ratio of present value of cash flow to the initial investment cost C_0 . If the project generates a larger present value of cash flow than initial cost, then PI > 1 and the project is worth doing.
